Topics:

- Reinforcement Learning Part 2
  - Deep Q Learning (cont.)
  - Policy Gradient
  - Actor-Critic
  - Advanced Policy Gradient Methods
- Applications
**What is Reinforcement Learning?**

- **Environment** may be unknown, non-linear, stochastic and complex.
- **Agent** learns a **policy** to map states of the environments to actions.
  - Seeking to maximize cumulative reward in the long run.

---

**RL:** Sequential decision making in an environment with evaluative feedback.

**Figure Credit:** Rich Sutton
- **MDPs**: Theoretical framework underlying RL

- An MDP is defined as a tuple \((S, A, R, T, \gamma)\)
  
  \(S\) : Set of possible states
  
  \(A\) : Set of possible actions
  
  \(R(s, a, s')\) : Distribution of reward
  
  \(T(s, a, s')\) : Transition probability distribution, also written as \(p(s'|s, a)\)
  
  \(\gamma\) : Discount factor

- **Experience**: \(\ldots s_t, a_t, r_{t+1}, S_{t+1}, a_{t+1}, r_{t+2}, S_{t+2}, \ldots\)

- **Markov property**: Current state completely characterizes state of the environment

- **Assumption**: Most recent observation is a sufficient statistic of history

  \[ p(S_{t+1} = s'|S_t = s_t, A_t = a_t, S_{t-1} = s_{t-1}, \ldots S_0 = s_0) = p(S_{t+1} = s'|S_t = s_t, A_t = a_t) \]
Algorithm: Value Iteration

- Initialize values of all states to arbitrary values, e.g., all 0’s.
- While not converged:
  - For each state:
    \[ V_{i+1}(s) \leftarrow \max_a \sum_{s'} p(s'|s,a) \left[ r(s,a) + \gamma V_i(s') \right] \]
  - Repeat until convergence (no change in values)

\[ V^0 \rightarrow V^1 \rightarrow V^2 \rightarrow \ldots \rightarrow V^i \rightarrow \ldots \rightarrow V^* \]

Time complexity per iteration \( O(|S|^2 |A|) \)
Q-Learning: a model-free method for RL

Idea: represent the Q value table as a parametric function $Q_\theta(s, a)$!

How do we learn the function?

$$Q'(s_t, a_t) = (1 - \alpha)Q(s_t, a_t) + \alpha[r_t + \gamma \max_a Q(s_{t+1}, a)]$$

$$= Q(s_t, a_t) + \alpha(r_t + \gamma \max_a Q(s_{t+1}, a) - Q(s_t, a_t))$$

Now, at optimum, $Q(s_t, a_t) = Q'(s_t, a_t) = Q^*(s_t, a_t)$; This gives us:

$$0 = 0 + \alpha(r_t + \gamma \max_a Q(s_{t+1}, a) - Q(s_t, a_t))$$

Learning problem:

$$\arg\min_\theta ||r_t + \gamma \max_a Q_\theta(s_{t+1}, a) - Q_\theta(s_t, a_t)||$$

Target Q value
Q-Learning with linear function approximators

\[ Q(s, a; w, b) = w_a^\top s + b_a \]

- Has some theoretical guarantees

Deep Q-Learning: Fit a deep Q-Network

- Works well in practice
- Q-Network can take arbitrary input (e.g. RGB images)
- Assume discrete action space (e.g., left, right)
Minibatch of \[ \{(s, a, s', r)\}_{i=1}^{B} \]

Forward pass:

\[ \text{State} \rightarrow \text{Q-Network} \rightarrow \text{Q-Values per action} \]
\[ B \times D \rightarrow B \times n_{actions} \]

Compute loss:
\[ \left( Q_{\text{new}}(s, a) - (r + \gamma \max_{a} Q_{\text{old}}(s', a)) \right)^2 \]
\[ \theta_{\text{new}} - \theta_{\text{old}} \]

Backward pass:
\[ \frac{\partial \text{Loss}}{\partial \theta_{\text{new}}} \]

Deep Q-Learning
MSE Loss := \left( Q_{new}(s, a) - (r + \max_{a} Q_{old}(s', a)) \right)^2

- In practice, for stability:
  - Freeze \( Q_{old} \) and update \( Q_{new} \) parameters
  - Set \( Q_{old} \leftarrow Q_{new} \) at regular intervals or update as running average
  - \( \theta_{old} = \beta \theta_{old} + (1 - \beta) \theta_{new} \)
How to gather experience?

Challenge 1: Exploration vs Exploitation

Challenge 2: Non iid, highly correlated data
What should $\pi_{\text{gather}}$ be?

- Greedy? $\rightarrow$ no exploration, always choose the most confident action
  \[ \arg\max_a Q(s, a; \theta) \]

- An exploration strategy:
  - $\epsilon$-greedy
  \[ a_t = \begin{cases} 
  \arg\max_a Q(s, a) & \text{with probability } 1 - \epsilon \\ 
  \text{random action} & \text{with probability } \epsilon 
  \end{cases} \]
Correlated data: addressed by using experience replay

- A replay buffer stores transitions \((s, a, s', r)\)
- Continually update replay buffer as game (experience) episodes are played, older samples discarded
- Train Q-network on random minibatches of transitions from the replay memory, instead of consecutive samples
- Larger the buffer, lower the correlation
Algorithm 1 Deep Q-learning with Experience Replay

Initialize replay memory $\mathcal{D}$ to capacity $N$ 
Initialize action-value function $Q$ with random weights
for episode = 1, $M$ do 
    Initialise sequence $s_1 = \{x_1\}$ and preprocessed sequenced $\phi_1 = \phi(s_1)$
    for $t = 1, T$ do
        With probability $\epsilon$ select a random action $a_t$
        otherwise select $a_t = \max_a Q^*(\phi(s_t), a; \theta)$
        Execute action $a_t$ in emulator and observe reward $r_t$ and image $x_{t+1}$
        Set $s_{t+1} = s_t, a_t, x_{t+1}$ and preprocessor $\phi_{t+1} = \phi(s_{t+1})$
        Store transition $(\phi_t, a_t, r_t, \phi_{t+1})$ in $\mathcal{D}$
        Sample random minibatch of transitions $(\phi_j, a_j, r_j, \phi_{j+1})$ from $\mathcal{D}$
        Set $y_j = \begin{cases} r_j & \text{for terminal } \phi_{j+1} \\ r_j + \gamma \max_{a'} Q(\phi_{j+1}, a'; \theta) & \text{for non-terminal } \phi_{j+1} \end{cases}$
        Perform a gradient descent step on $(y_j - Q(\phi_j, a_j; \theta))^2$ according to equation 3
    end for
end for

Deep Q-Learning Algorithm

Experience Replay
Epsilon-greedy
Q Update
Atari Games

- **Objective**: Complete the game with the highest score
- **State**: Raw pixel inputs of the game state
- **Action**: Game controls e.g. Left, Right, Up, Down
- **Reward**: Score increase/decrease at each time step

Summary: Value-based RL

• Solving an MDP by modeling / learning the values (Q and V) of an optimal policy
• Examples: Value iteration, Q learning, DQN, SARSA, TD(0), ...
• Pros:
  – Conceptually simple
  – Efficient in discrete action space
• Cons:
  – Handling continuous / large action space is challenging.
  – A proxy of what we actually want (a policy)
Different RL Paradigms

- **Value-based RL**
  - (Deep) Q-Learning, approximating $Q^*(s, a)$ with a deep Q-network

- **Policy-based RL**
  - Directly approximate optimal policy $\pi^*$ with a parametrized policy $\pi^*_\theta$

- **Model-based RL**
  - Approximate transition function $T(s', a, s)$ and reward function $R(s, a)$
  - Plan by looking ahead in the (approx.) future!
Problem: we don’t know the correct action label to supervise the output!
All we know is the step-wise task reward
Deep Learning for Decision Making

Problem: we don’t know the correct action label to supervise the output!
All we know is the step-wise task reward
Can we directly backprop reward???
Policy Gradient: Just backprop from reward (sort of)!

Supervised Learning (correct label is provided)

Increase the likelihood of selecting action dim = 0!

Image Source: http://karpathy.github.io/2016/05/31/rl/
Policy Gradient: Just backprop from reward (sort of)!

Forward pass:
- Image
- Block of differentiable compute (e.g. neural net)

Backward pass:
- Log probabilities:
  - Action 0: -1.2
  - Action 1: -0.36
- Gradients:
  - Action 0: 1.0
  - Action 1: 0

Supervised Learning:
- Correct action label: 0
- Increase the likelihood of selecting action dim = 0!

Policy Gradient:
- Sample an action: sampled action = 1
- Eventual reward: -1.0
- Decrease the likelihood of selecting action dim = 1!
Brief derivation of policy gradient (REINFORCE)

Let $\tau = (s_0, a_0, \ldots, s_T, a_T)$ denote a trajectory.
Brief derivation of policy gradient (REINFORCE)

Let $\tau = (s_0, a_0, \ldots s_T, a_T)$ denote a trajectory.

Distribution of trajectories given a policy parameterized by $\theta$ is:

$$p_{\theta}(\tau) = p_{\theta}(s_0, a_0, \ldots s_T, a_T) = p(s_0) \prod_{t=0}^{T} p_{\theta}(a_t | s_t) \cdot p(s_{t+1} | s_t, a_t)$$
Brief derivation of policy gradient (REINFORCE)

Let \( \tau = (s_0, a_0, \ldots, s_T, a_T) \) denote a trajectory.

- Distribution of trajectories given a policy parameterized by \( \theta \) is:
  \[
  p_\theta(\tau) = p_\theta(s_0, a_0, \ldots, s_T, a_T) = p(s_0) \prod_{t=0}^{T} p_\theta(a_t | s_t) \cdot p(s_{t+1} | s_t, a_t)
  \]

- Optimization objective:
  \[
  \arg \max_{\theta} \mathbb{E}_{\tau \sim p_\theta(\tau)} [\mathcal{R}(\tau)]
  \]
**Brief derivation of policy gradient (REINFORCE)**

Let \( \tau = (s_0, a_0, \ldots s_T, a_T) \) denote a trajectory.

- Distribution of trajectories given a policy parameterized by \( \theta \) is:
  \[
p_\theta(\tau) = p_\theta(s_0, a_0, \ldots s_T, a_T) = p(s_0) \prod_{t=0}^T p_\theta(a_t | s_t) \cdot p(s_{t+1} | s_t, a_t)
  \]

- Optimization objective:
  \[
  \arg \max_\theta \mathbb{E}_{\tau \sim p_\theta(\tau)} [\mathcal{R}(\tau)]
  \]

- What we need (policy gradient):
  \[
  \nabla_\theta J(\theta) = \nabla_\theta \mathbb{E}_{\tau \sim p_\theta(\tau)} [\mathcal{R}(\tau)]
  \]
Brief derivation of policy gradient (REINFORCE)

\[
\nabla_\theta J(\theta) = \nabla_\theta \mathbb{E}_{\tau \sim p_\theta(\tau)}[R(\tau)]
\]

\[
= \nabla_\theta \int \pi_\theta(\tau) R(\tau) d\tau
\]

Expectation as integral

\[
= \int \nabla_\theta \pi_\theta(\tau) R(\tau) d\tau
\]

Exchange integral and gradient

\[
= \int \nabla_\theta \pi_\theta(\tau) \cdot \frac{\pi_\theta(\tau)}{\pi(\tau)} \cdot R(\tau) d\tau
\]

Log derivative rule: \( \frac{d \log f(x)}{dx} = \frac{f'(x)}{x} \)

\[
= \int \pi_\theta(\tau) \nabla_\theta \log \pi_\theta(\tau) R(\tau) d\tau
\]

\[
= \mathbb{E}_{\tau \sim p_\theta(\tau)}[\nabla_\theta \log \pi_\theta(\tau) R(\tau)]
\]
Brief derivation of policy gradient (REINFORCE)

\[ \nabla_{\theta} J(\theta) = \mathbb{E}_{\tau \sim p_\theta(\tau)} \left[ \nabla_{\theta} \log \pi_\theta(\tau) R(\tau) \right] \]

\[ \nabla_{\theta} \left[ \log p(s_0) + \sum_{t=1}^{T} \log \pi_\theta(a_t | s_t) + \sum_{t=1}^{T} \log p(s_{t+1} | s_t, a_t) \right] \]

\[ = \mathbb{E}_{\tau \sim p_\theta(\tau)} \left[ \sum_{t=1}^{T} \nabla_{\theta} \log \pi_\theta(a_t | s_t) \cdot \sum_{t=1}^{T} R(s_t, a_t) \right] \]

\[ \pi_\theta(\tau) = p(s_0) \prod_{t=0}^{T} p_\theta(a_t | s_t) \cdot p(s_{t+1} | s_t, a_t) \]

Doesn’t depend on Transition probabilities!

Can use continuous action space!
Policy gradient: algorithm sketch

- Sample trajectories $\tau_i = \{s_1, a_1, \ldots s_T, a_T\}_i$ by acting according to $\pi_{\theta}$

- Compute policy gradient as

$$\nabla_{\theta} J(\theta) \approx \frac{1}{N} \sum_{i}^{N} \left[ \sum_{t=1}^{T} \nabla_{\theta} \log \pi_{\theta} \left( a_t^i \mid s_t^i \right) \cdot \sum_{t=1}^{T} R \left( s_t^i \mid a_t^i \right) \right]$$

- Update policy parameters: $\theta \leftarrow \theta + \alpha \nabla_{\theta} J(\theta)$
Policy gradient intuition

\[ \log \pi_\theta(a|s) \]
Issues with Policy Gradients

• **Credit assignment is hard!**
  – Which specific action led to increase in reward
  – Suffers from high variance $\rightarrow$ leading to unstable training

Can we do better?

What if instead of just reward per episode, we know the expected future return of taking an action? (This should remind you of something ...)

$Q$ value function $Q(s, a)!$
Actor-Critic

• Learn both policy and Q function
  – Use the “actor” to sample trajectories
  – Use the Q function to “evaluate” or “critic” the policy
Actor-Critic

• Learn both policy and Q function
  – Use the “actor” to sample trajectories
  – Use the Q function to “evaluate” or “critic” the policy

• REINFORCE: \[ \nabla_\theta J(\pi_\theta) = \mathbb{E}_{a \sim \pi_\theta} [\nabla_\theta \log \pi_\theta(a|s) R(s, a)] \]

• Actor-critic: \[ \nabla_\theta J(\pi_\theta) = \mathbb{E}_{a \sim \pi_\theta} [\nabla_\theta \log \pi_\theta(a|s) Q^{\pi_\theta}(s, a)] \]
Actor-Critic

- Initialize $\theta$ (policy network) and $\beta$ (Q network)
Actor-Critic

• Initialize $\theta$ (policy network) and $\beta$ (Q network)
• For each step:
  – sample action $a \sim \pi_\theta(\cdot |s)$, take action to get $s'$ and $r$
Actor-Critic

- Initialize $\theta$ (policy network) and $\beta$ (Q network)
- For each step:
  - sample action $a \sim \pi_\theta (\cdot | s)$, take action to get $s'$ and $r$
  - evaluate “actor” using “critic” $Q_\beta (s, a)$ and update policy:

$$\theta \leftarrow \theta + \alpha \nabla_\theta (\log \pi_\theta (a | s) Q_\beta (s, a))$$
Actor-Critic

• Initialize $\theta$ (policy network) and $\beta$ (Q network)

• For each step:
  – sample action $a \sim \pi_\theta (\cdot |s)$, take action to get $s'$ and $r$
  – evaluate “actor” using “critic” $Q_\beta (s, a)$ and update policy:
    \[
    \theta \leftarrow \theta + \alpha \nabla_\theta (\log \pi_\theta (a|s)Q_\beta (s, a))
    \]
  – Update “critic”:
    • Q-learning using $\arg\min_\beta [Q_\beta (s, a) - (r + Q(s', a \sim \pi_\theta (s')))]]$
Actor-Critic

- Initialize $\theta$ (policy network) and $\beta$ (Q network)
- For each step:
  - sample action $a \sim \pi_\theta(\cdot | s)$, take action to get $s'$ and $r$
  - evaluate “actor” using “critic” $Q_\beta(s, a)$ and update policy:
    \[
    \theta \leftarrow \theta + \alpha \nabla_\theta \left( \log \pi_\theta(a | s) Q_\beta(s, a) \right)
    \]
  - Update “critic”:
    - Q-learning using $\arg\min_\beta [Q_\beta(s, a) - (r + Q(s', a \sim \pi_\theta(s'))) ]$

Note the difference to DQN:
\[\left( Q_{new}(s, a) - (r + \gamma \max_a Q_{old}(s', a)) \right)^2 \]
Actor-Critic

Actor-critic Policy Gradient: $\nabla_{\theta} J(\pi_{\theta}) = E_{a \sim \pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(a|s)Q_{\beta}(s, a)]$
Actor-Critic

Actor-critic Policy Gradient: $\nabla_\theta J(\pi_\theta) = E_{a \sim \pi_\theta} [\nabla_\theta \log \pi_\theta (a | s) Q_\beta (s, a)]$

Consider a situation where $Q_\beta (s, a_1) = 10.1$ and $Q_\beta (s, a_2) = 10.5$
Actor-Critic

Actor-critic Policy Gradient: \( \nabla_\theta J(\pi_\theta) = E_{a \sim \pi_\theta} [\nabla_\theta \log \pi_\theta (a|s) Q_\beta (s, a)] \)

Consider a situation where \( Q_\beta (s, a_1) = 10.1 \) and \( Q_\beta (s, a_2) = 10.5 \)
– Good news: \( s \) is a great state to be in!
Actor-Critic

Actor-critic Policy Gradient: \( \nabla_{\theta} J(\pi_{\theta}) = E_{a \sim \pi_{\theta}}[\nabla_{\theta} \log \pi_{\theta}(a|s)Q_{\beta}(s, a)] \)

Consider a situation where \( Q_{\beta}(s, a_1) = 10.1 \) and \( Q_{\beta}(s, a_2) = 10.5 \)
- Good news: \( s \) is a great state to be in!
- Bad news: hard to tell the policy to prefer \( a_2 \) over \( a_1 \)
Actor-Critic

Actor-critic Policy Gradient: \( \nabla_{\theta} J(\pi_\theta) = E_{a \sim \pi_\theta}[\nabla_{\theta} \log \pi_\theta(a|s)Q_\beta(s, a)] \)

Consider a situation where \( Q_\beta(s, a_1) = 10.1 \) and \( Q_\beta(s, a_2) = 10.5 \)

- Good news: \( s \) is a great state to be in!
- Bad news: hard to tell the policy to prefer \( a_2 \) over \( a_1 \)

Idea: use \textit{advantage function} \( A(s, a) = Q(s, a) - V(s) \)
Actor-Critic

Actor-critic Policy Gradient: \( \nabla_{\theta} J(\pi_{\theta}) = E_{a \sim \pi_{\theta}}[\nabla_{\theta} \log \pi_{\theta}(a|s)Q_{\beta}(s, a)] \)

Consider a situation where \( Q_{\beta}(s, a_1) = 10.1 \) and \( Q_{\beta}(s, a_2) = 10.5 \)

– Good news: \( s \) is a great state to be in!
– Bad news: hard to tell the policy to prefer \( a_2 \) over \( a_1 \)

Idea: use advantage function \( A(s, a) = Q(s, a) - V(s) \)
- \( A(s, a) \): How much better is taking action \( a \) over the average value at state \( s \)
Actor-Critic

Actor-critic Policy Gradient: $\nabla_{\theta} J(\pi_{\theta}) = \mathbb{E}_{a \sim \pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(a|s) Q_{\beta}(s, a)]$

Consider a situation where $Q_{\beta}(s, a_1) = 10.1$ and $Q_{\beta}(s, a_2) = 10.5$

- Good news: $s$ is a great state to be in!
- Bad news: hard to tell the policy to prefer $a_2$ over $a_1$

Idea: use advantage function $A(s, a) = Q(s, a) - V(s)$

- $A(s, a)$: How much better is taking action $a$ over the average value at state $s$
- Say $V(s) = 10.0$, we have $A(s, a_1) = 0.1$ and $A(s, a_2) = 0.5$
Advantage Actor-Critic (A2C)

Advantage Actor-critic Gradient: $\nabla_{\theta} J(\pi_{\theta}) = E_{a \sim \pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(a|s)A(s, a)]$
Advantage Actor-Critic (A2C)

Advantage Actor-critic Gradient: \( \nabla_\theta J(\pi_\theta) = E_{a \sim \pi_\theta} [\nabla_\theta \log \pi_\theta(a|s)A(s, a)] \)

Problem: need to learn both \( Q \) and \( V \) to calculate \( A \)
Advantage Actor-Critic (A2C)

Advantage Actor-critic Gradient: $\nabla_\theta J(\pi_\theta) = E_{a \sim \pi_\theta} [\nabla_\theta \log \pi_\theta (a|s)A(s, a)]$

Problem: need to learn both $Q$ and $V$ to calculate $A$

Idea: use state value of experience sample to approximate $Q$:
Given experience $(s, a, r, s')$
$$A(s, a) = Q(s, a) - V(s) \approx r + V(s') - V(s)$$
Policy Gradient Methods

• REINFORCE: $\nabla_{\theta} J(\pi_{\theta}) = E_{a \sim \pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(a|s) R(s, a)]$

• Actor-critic (AC): $\nabla_{\theta} J(\pi_{\theta}) = E_{a \sim \pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(a|s) Q(s, a)]$

• Advantage Actor-critic (A2C): $\nabla_{\theta} J(\pi_{\theta}) = E_{a \sim \pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(a|s) A(s, a)]$
Welcome to continuous control!

\[ \nabla_{\theta} J(\pi_{\theta}) = \mathbb{E}_{a \sim \pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(a|s)A(s,a)] \]

Policy net can output anything!

DQN: limited to discrete action space

Q-Network

\begin{align*}
\text{FC-4 (Q-values)} & \\
\text{FC-256} & \\
32 \ 4x4 \ \text{conv, stride 2} & \\
16 \ 8x8 \ \text{conv, stride 4} & 
\end{align*}

State
Policy Gradient Methods

• REINFORCE: $\nabla_\theta J(\pi_\theta) = E_{a \sim \pi_\theta}[\nabla_\theta \log \pi_\theta(a|s)R(s,a)]$

• Actor-critic (AC): $\nabla_\theta J(\pi_\theta) = E_{a \sim \pi_\theta}[\nabla_\theta \log \pi_\theta(a|s)Q(s,a)]$

• Advantage Actor-critic (A2C): $\nabla_\theta J(\pi_\theta) = E_{a \sim \pi_\theta}[\nabla_\theta \log \pi_\theta(a|s)A(s,a)]$

Common Policy Gradient methods are on-policy.
On-policy vs. off policy algorithms

- REINFORCE: $\nabla_\theta J(\pi_\theta) = E_{a \sim \pi_\theta}[\nabla_\theta \log \pi_\theta(a|s)R(s, a)]$
  
  We are taking expectation wrt the policy being learned

Cannot use replay buffer, since the experience data is an outdated policy.
- Less data-efficient: cannot reuse old data
- Less stable to train: explore may lead to bad on-policy data -> immediate performance degradation.
- Correlated samples in training data.

Example of an off-policy learning algorithm: DQN

$$Q'(s_t, a_t) = Q(s_t, a_t) + \alpha (r_t + \gamma \max_a Q(s_{t+1}, a) - Q(s_t, a_t))$$

Bellman equation is true for all transitions!
Deep Deterministic Policy Gradient (DDPG)

A direct adaptation of DQN for continuous action space

Learning the critic (value function): bellman consistency

\[
\min_\beta [Q_\beta (s, a) - \left( r + \max_a Q(s', a) \right)]
\]

Q: What’s the problem with this objective? Difficult to compute for continuous action space!
Deep Deterministic Policy Gradient (DDPG)

A direct adaptation of DQN for continuous action space

Learning the critic (value function): bellman consistency

\[
\min_\beta [Q_\beta(s, a) - (r + \max_a Q(s', a))]
\]

Idea: approximate with a deterministic policy
\[
\max_a Q(s', a) \approx Q(s', \pi(s))
\]
Deep Deterministic Policy Gradient (DDPG)

A direct adaptation of DQN for continuous action space

Learning the critic (value function): bellman consistency

\[ \min_\beta [Q_\beta (s, a) - (r + Q_{old}(s', \pi(s')))] \]

Deterministic policy gradient theorem (off-policy)

Gradient of Q wrt to action

\[ \nabla_\theta J(\pi_\theta) \approx \mathbb{E}_{s \sim \rho^*} [\nabla_\theta \log \pi_\theta(s) \nabla_a Q(s, a)] \]

We are taking expectation wrt a behavior policy (replay buffer)

Learning the actor (policy model):

\[ \max_\theta \mathbb{E}_{s \sim \rho^*} [Q_\beta (s, \pi_\theta(s))] \]

Just back prop to policy from the value function!
A2C vs. DDPG

• Two related families of algorithms.
• A2C is on-policy. Learn advantage-based critic. Train policy through the policy gradient theorem (REINFORCE).
• DDPG is off-policy (train on replay buffer). Learn value-based critic. Train policy through direct backpropagation from critic to actor based on the deterministic policy gradient theorem.
• **Drawback:** DDPG is deterministic and often struggles with exploration.
Advanced policy gradient methods

Soft Actor Critic (Haarnoja, 2018)

Entropy-regularized RL: achieve high reward while being as random as possible

$$\pi^* = \arg \max_{\pi} \mathbb{E}_{\tau \sim \pi} \left[ \sum_{t=0}^{\infty} \gamma^t \left( R(s_t, a_t, s_{t+1}) + \alpha H(\pi(\cdot|s_t)) \right) \right],$$

Bellman equation with entropy-regularized RL:

$$Q^\pi(s, a) \approx r + \gamma \left( Q^\pi(s', \tilde{a}') - \alpha \log \pi(\tilde{a}'|s') \right), \quad \tilde{a}' \sim \pi(\cdot|s').$$

Entropy of the policy
Advanced policy gradient methods

**Soft Actor Critic** (Haarnoja, 2018)

Learning the policy model:

\[ V^\pi(s) = \mathbb{E}_{a \sim \pi} [Q^\pi(s, a)] + \alpha H(\pi(\cdot | s)) \]

\[ = \mathbb{E}_{a \sim \pi} [Q^\pi(s, a) - \alpha \log \pi(a | s)] . \]

Requires integrating a distribution!

Reparameterization trick (truncated Gaussian):

\[ \tilde{a}_\theta(s, \xi) = \tanh (\mu_\theta(s) + \sigma_\theta(s) \odot \xi) , \quad \xi \sim \mathcal{N}(0, I). \]

Backprop through the value function (same as DDPG):

\[ \mathbb{E}_{a \sim \pi_\theta} [Q^{\pi_\theta}(s, a) - \alpha \log \pi_\theta(a | s)] = \mathbb{E}_{\xi \sim \mathcal{N}} [Q^{\pi_\theta}(s, \tilde{a}_\theta(s, \xi)) - \alpha \log \pi_\theta(\tilde{a}_\theta(s, \xi) | s)] \]
Advanced policy gradient methods

Trust Region Policy Gradient (TRPO, Schulman 2017)
Advanced policy gradient methods

**Trust Region Policy Gradient** (TRPO, Schulman 2017)

- Issue with vanilla actor critic: policy may receive huge update!
  - Big parameter update -> drastic change in behavior -> may stuck in low-reward region!
Advanced policy gradient methods

Trust Region Policy Gradient (TRPO, Schulman 2017)

- Issue with vanilla actor critic: policy may receive huge update!
  - Big parameter update -> drastic change in behavior -> may stuck in low-reward region!
Advanced policy gradient methods

Trust Region Policy Gradient (TRPO, Schulman 2017)

• Issue with vanilla actor critic: policy may receive huge update!
  – Big parameter update -> drastic change in behavior -> may stuck in low-reward region!

• Idea: constrain the update to a trust region using off-policy policy gradient

\[
J(\theta) = \mathbb{E}_{s \sim \rho^{\pi_{\theta_{\text{old}}}}, a \sim \pi_{\theta_{\text{old}}}} \left[ \frac{\pi_{\theta}(a|s)}{\pi_{\theta_{\text{old}}}(a|s)} \hat{A}_{\theta_{\text{old}}}(s,a) \right]
\]
Advanced policy gradient methods

**Trust Region Policy Gradient** (TRPO, Schulman 2017)

- Issue with vanilla actor critic: policy may receive huge update!
  - Big parameter update -> drastic change in behavior -> may stuck in low-reward region!

- Idea: constrain the update to a *trust region* using off-policy policy gradient

\[
J(\theta) = \mathbb{E}_{s \sim \rho^{\pi_{\text{old}}}, a \sim \pi_{\text{old}}} \left[ \frac{\pi_{\theta}(a|s)}{\pi_{\text{old}}(a|s)} \hat{A}_{\text{old}}(s,a) \right]
\]

Subject to:

\[
\mathbb{E}_{s \sim \rho^{\pi_{\text{old}}}} [D_{KL}(\pi_{\text{old}}(\cdot|s) || \pi_{\theta}(\cdot|s))] \leq \delta
\]
Advanced policy gradient methods

**Trust Region Policy Gradient** (TRPO, Schulman 2017)

- Issue with vanilla actor critic: policy may receive huge update!
  - Big parameter update -> drastic change in behavior -> may stuck in low-reward region!

- Idea: constrain the update to a *trust region* using off-policy policy gradient

\[
J(\theta) = \mathbb{E}_{s \sim \rho^{\pi_{\text{old}}}, a \sim \pi_{\text{old}}} \left[ \frac{\pi_\theta(a|s)}{\pi_{\text{old}}(a|s)} \hat{A}_{\text{old}}(s, a) \right]
\]

Subject to:

\[
\mathbb{E}_{s \sim \rho^{\pi_{\text{old}}}} [D_{\text{KL}}(\pi_{\theta_{\text{old}}}(\cdot|s) || \pi_\theta(\cdot|s))] \leq \delta
\]

Optimizing this objective requires calculating Hessian (second-order optimization)!
Advanced policy gradient methods

**Proximal Policy Optimization** (PPO, Schulman 2017)
Issue with TRPO: objective too complicated! Requires second-order optimization (calculating Hessian).
**Advanced policy gradient methods**

**Proximal Policy Optimization** (PPO, Schulman 2017)

Issue with TRPO: objective too complicated! Requires second-order optimization (calculating Hessian).

Idea: Approximate trust-region constraint with a penalty term

\[
\max_{\theta} \quad \hat{E}_t \left[ \frac{\pi_\theta(a_t | s_t)}{\pi_{\theta_{old}}(a_t | s_t)} \hat{A}_t \right] - \beta \hat{E}_t [\text{KL}[\pi_{\theta_{old}}(\cdot | s_t), \pi_\theta(\cdot | s_t)]]
\]
Advanced policy gradient methods

Schulman 2017
But Deep RL is still pretty expensive to train …

Idea: transfer policy trained in simulation (cheap) directly to the real world (expensive)!
Simulation to Real World Transfer (Sim2Real)

Issue: simulators is a very crude approximation of the real world!
Simulation to Real World Transfer (Sim2Real)

Issue: simulators is a very crude approximation of the real world!

Potential gaps (not an exhaustive list):
- Position, shape, and color of objects,
- Material texture,
- Lighting condition,
- Other measurement noise,
- Position, orientation, and field of view of the camera in the simulator.
- Mass and dimensions of objects,
- Mass and dimensions of robot bodies,
- Damping, kp, friction of the joints,
- Gains for the PID controller (P term),
- Joint limit,
- Action delay,
Simulation to Real World Transfer (Sim2Real)

Issue: simulators is a very crude approximation of the real world!

Idea: domain randomization

Summary

• It turns out we *can* directly backprop from reward (sort of)!
• Naïve policy gradient (REINFORCE) has high variance due to the use of episodic reward. Credit assignment is hard.
• Use Action Value Function (Q) instead!
  – Actor-Critic: learn Q value function jointly with policy
  – Advantage Actor-Critic: estimate advantage A using V value function
  – Deep Deterministic Policy Gradient for off-policy learning
  – SAC for off-policy learning with stochastic policy model
• Other advanced policy gradient methods: TRPO, PPO
• Still pretty expensive to train! Mostly used for application that can be simulated.
