home.but he got lonely.
he wanted his mom.he
wanted his dad.so
he went home.

the end.

PIANOS not STEREOS

CREATING COMPUTATIONAL CONSTRUCTION KITS

Mitchel Resnick, Amy Bruckman, and Fred Martin

Would you rather that your children learn to play the piano, or learn to play the stereo?

THE STEREO HAS MANY ATTRACTIONS: IT IS EASIER THAN THE PIANO TO PLAY, AND IT PROVIDES IMMEDIATE ACCESS TO A WIDE RANGE OF MUSIC. BUT "EASE OF USE" SHOULD NOT BE THE ONLY CRITERION. PLAYING THE PIANO CAN BE A MUCH RICHER EXPERIENCE. BY LEARNING TO PLAY THE PIANO, YOU CAN BECOME A CREATOR, NOT JUST A CONSUMER, OF MUSIC, EXPRESSING YOURSELF MUSICALLY IN INCREASINGLY EVER-MORE COMPLEX WAYS. AS A RESULT, YOU CAN DEVELOP A MUCH DEEPER RELATIONSHIP WITH (AND DEEPER UNDERSTANDING OF) MUSIC.

So, too, with computers. Educational technology has too heavily emphasized the equivalent of stereos and CDs and not emphasized computational pianos enough. In our research group at the MIT Media Lab, we are developing a new generation of "computational construction kits" that, like pianos, enable people to express themselves in increasingly ever-more complex ways, deepening their relationships with new domains of knowledge.

To guide the development of these computational construction kits, we are developing a theory of constructional design. Whereas the traditional field of instructional design focuses on strategies and materials to help teachers instruct, our theory of constructional design focuses on strategies and materials to help students construct and learn. Constructional design is a type of metadesign: it involves the design of new tools and activities to support students in their own design activities. In short, constructional design involves designing for designers [12].

In recent years, a growing number of researchers and educators have argued that design projects provide rich opportunities for learning [3, 5, 14]. In particular, Papert [8] has argued for a "constructionist" approach to learning. There are many reasons for this interest in design-based learning. Design activities involve people as active participants, giving them a greater sense of control over (and personal involvement in) the learning process. Moreover, the things that people design (be they sand castles, computer programs, LEGO constructions, or musical compositions) serve as external shadows of the designer's internal mental models. These external creations provide an opportunity for people to reflect on—and then revise and extend—their internal models of the world.

> Educational technology has too heavily emphasized the equivalent of stereos and CDs and not emphasized computational pianos

Of course, not all design experiences (or all construction kits) are created equal. Some provide richer learning opportunities than others. What criteria should guide the design of new construction kits and activities? The concept of learning-by-doing has existed for a long time. But the literature on the subject tends to describe specific activities and gives little attention to the general principles governing the kinds of "doing" most conducive to learning. From our experiences, we have developed two general principles to guide the design of new construction kits and activities. These constructional-design principles involve two different types of "connections":

- *Personal connections.* Construction kits and activities should connect to users' interests, passions, and experiences. The point is not simply to make the activities more "motivating." When activities involve objects and actions that are familiar, users can draw on their previous knowledge, connecting new ideas to their pre-existing intuitions.

- *Epistemological connections.* Construction kits and activities should connect to important domains of knowledge—and, more significantly, encourage new ways of thinking (and even new ways of thinking about thinking). A well-designed construction kit makes certain ideas and ways of thinking particularly salient, so that users are likely to connect with those ideas in a natural way in the process of designing and creating.

The challenge of constructional design—and it is a significant challenge—is to create construction kits with both types of connections. Many learning materials and activities offer one type of connection but not the other. In this article, we discuss three of our computational construction kits. In each case, we discuss how the kit aims to facilitate both personal and epistemological connections—and, as a result, support rich learning experiences.

PROGRAMMABLE BRICKS

Traditional construction kits enable children to build structures and mechanisms such as castles and cars. The programmable brick adds a new level of construction, enabling children to build behaviors.

The programmable brick is a tiny computer embedded inside a LEGO® brick. Children can build programmable bricks directly into their LEGO constructions and then write programs to make their creations react, behave, and collect data. Some children have used programmable bricks to build autonomous LEGO "creatures" that mimic the behaviors of real animals (see Figure 1). Others have used programmable bricks to conduct new types of science experiments, investigating phenomena in their everyday lives. One 13-year-old boy connected a sensor to his leg and programmed a programmable brick in his pocket to track the number of steps he took during a day. Another pair of students used programmable bricks to make a "smart room." When anyone entered the room, the brick mechanically flipped on the light switch; when the last person left the room, it turned off the light.

To program the brick, children write programs on a personal computer, then download the

programs via a cable to the programmable brick. After that, they can disconnect the brick and take it or put it anywhere. The programs remain stored in the brick. The brick can control four motors at a time, receive inputs from six sensors, and communicate with other electronic devices via infrared communications.

The programmable brick can be seen as a "very personal computer." One version of the brick is about the size of a child's juice box. It is the right size for a kid's computer; a laptop seems too big in comparison. The programmable brick has strong personal connections to children's lives. Toys in general, and LEGO building materials in particular, are part of children's culture. When programmable bricks are added to the bin of LEGO building parts, computation becomes part of children's culture too.

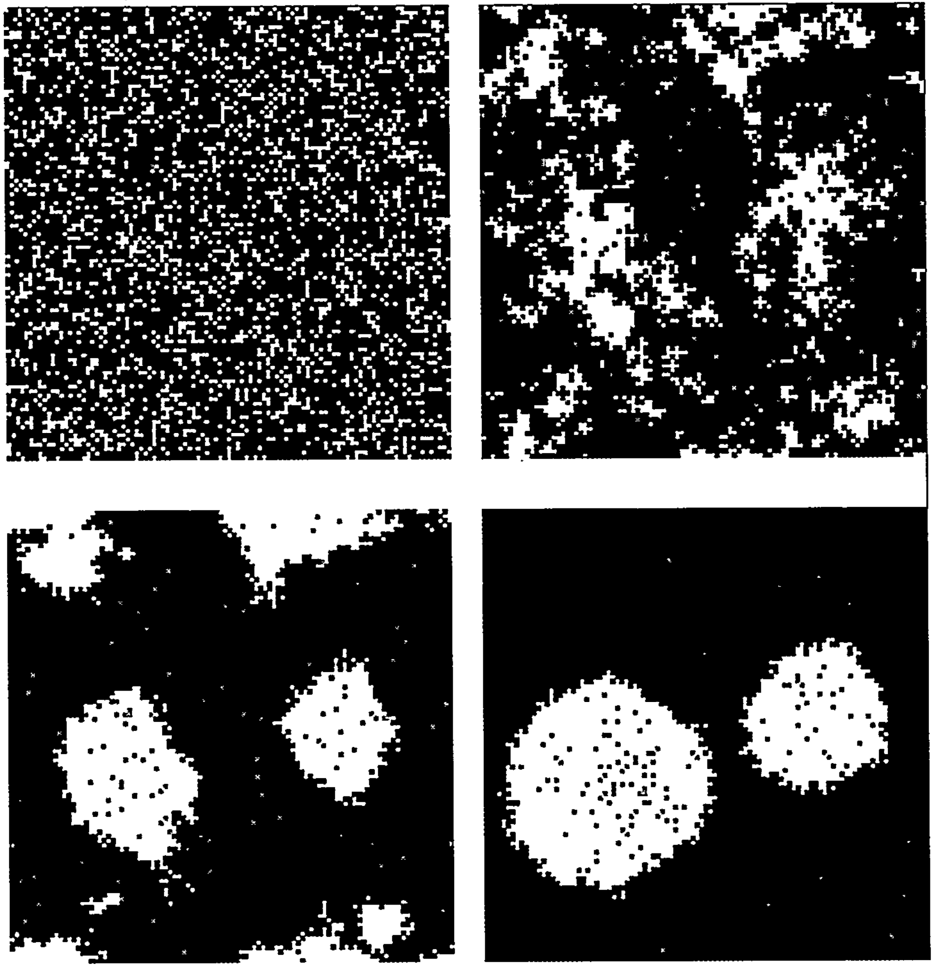
At the same time, programmable bricks have strong epistemological connections. When students build and program robotic creatures, for example, they often wonder about the similarities and differences between animals and machines. Are their LEGO creatures like animals? Or like machines? They compare their robots' sensors to animal senses, and they discuss whether real animals have "programs" like their robots.

In one fifth-grade class, students created a LEGO dinosaur that was attracted to flashes of light, like one of the dinosaurs in Jurassic Park. This project had a clear connection to popular culture. But it also had a direct connection to scientific culture. To make the dinosaur move toward the light, the students needed to understand basic ideas about feedback and control. The program compared readings from the dinosaur's two light-sensor "eyes." If the dinosaur drifted too far to the left (i.e., more light in the right eye), the program made it veer back to the right; if the dinosaur went too far right (more light in the left eye), the program corrected it to move toward the left. This classic feedback strategy is typically not taught until university-level courses. But with the right tools, fifth graders were able to explore these ideas.

The programmable brick project is part of a larger Media Lab initiative known as Things That Think. The project relates to a field of research sometimes called "ubiquitous computing" [17, 18]. The overarching goal in this research is to embed computational capabilities in everyday objects such as furniture, shoes, and toys—mixing together "bits" and "atoms." The programmable brick fits within this initiative, but with an important twist. In our research, we are interested in Things That Think not because they might accomplish particular tasks more cheaply or easily or intelligently, but because they might enable people to think about things in new ways. That is, Things That Think are most interesting to us when they also act as Things To Think With. We believe that programmable bricks act in just that way. By enabling children to build their own Things That Think (such as the light-seeking dinosaur), programmable bricks involve children in new types of thinking.

LEGO is a registered trademark of the LEGO group.

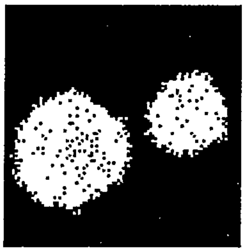
STARLOGO



Whereas programmable bricks enable students to embed computers in the world, StarLogo enables them to construct worlds in the computer.

In particular, StarLogo is designed to help students model and explore the behaviors of decentralized systems—such as ant colonies, traffic jams, market economies, immune systems, and computer networks. In these systems, orderly patterns arise without centralized control. In ant colonies, for example, trail patterns are determined not by the dictates of the queen ant but by local interactions among the worker ants. In market economies, patterns arise from interactions among millions of buyers and sellers in distributed marketplaces.

Decentralized systems are important throughout the sciences and social sciences, but most people have difficulty understanding the workings of such systems. People seem to have strong attachments to centralized ways of thinking. When people see patterns in the world (such as the foraging



patterns of an ant colony), they generally assume that there is some type of centralized control (a queen ant). According to this way of thinking, a pattern can exist only if someone (or something) creates and orchestrates the pattern.

StarLogo is designed to help students make a fundamental epistemological shift, to move beyond the "centralized mindset" to more decentralized ways of thinking [10, 11]. StarLogo allows students to construct and experiment with decentralized systems. They write simple rules for thousands of objects (e.g., artificial ants), then observe the patterns (e.g., colony-level foraging patterns) that arise from all of the interactions. By creating their own StarLogo models, students can build on personal connections. For example, two high-school students who had recently received their drivers' licenses used StarLogo to model the formation of traffic jams on the highway—a topic of great interest to them. They discovered (counter to their initial intuitions) how traffic jams can form through simple, decentralized interactions among cars, without any centralized cause such as an accident, radar trap, or broken bridge.

Another high-school student named Callie used StarLogo to model the workings of a termite colony (see Figure 2). Callie had seen a television program that showed termites building intricate structures on the plains of Africa. She wondered how creatures as simple as termites could build such elaborate structures. She decided to program a colony of virtual termites to gather wood chips into a pile. At first, Callie tried to put one termite in charge and programmed that termite to tell all of the other termites where to put the wood chips. But it is difficult to establish that type of centralized control in StarLogo. We discussed some of the drawbacks of a centralized leader: What would happen, for instance, if the leader termite was killed? Callie experimented with more decentralized approaches (more in line with the underlying structure of StarLogo) and found that the colony didn't need a leader after all. In her final model, each termite followed the same set of simple rules: wander randomly until you bump into a wood chip, pick up the wood chip, wander randomly until you bump into another wood chip, put down the wood chip you're carrying, start over. This strategy uses only local sensory information and a simple control strategy, but the group as a whole accomplishes a sophisticated task.

Traditionally, these types of complex decentralized systems have been studied only at the university level, using differential equations and other advanced mathematical techniques. StarLogo enables much younger students to explore these systems—and to gain an understanding of the underlying ideas of self-organizing [10] and probabilistic [19] behavior.

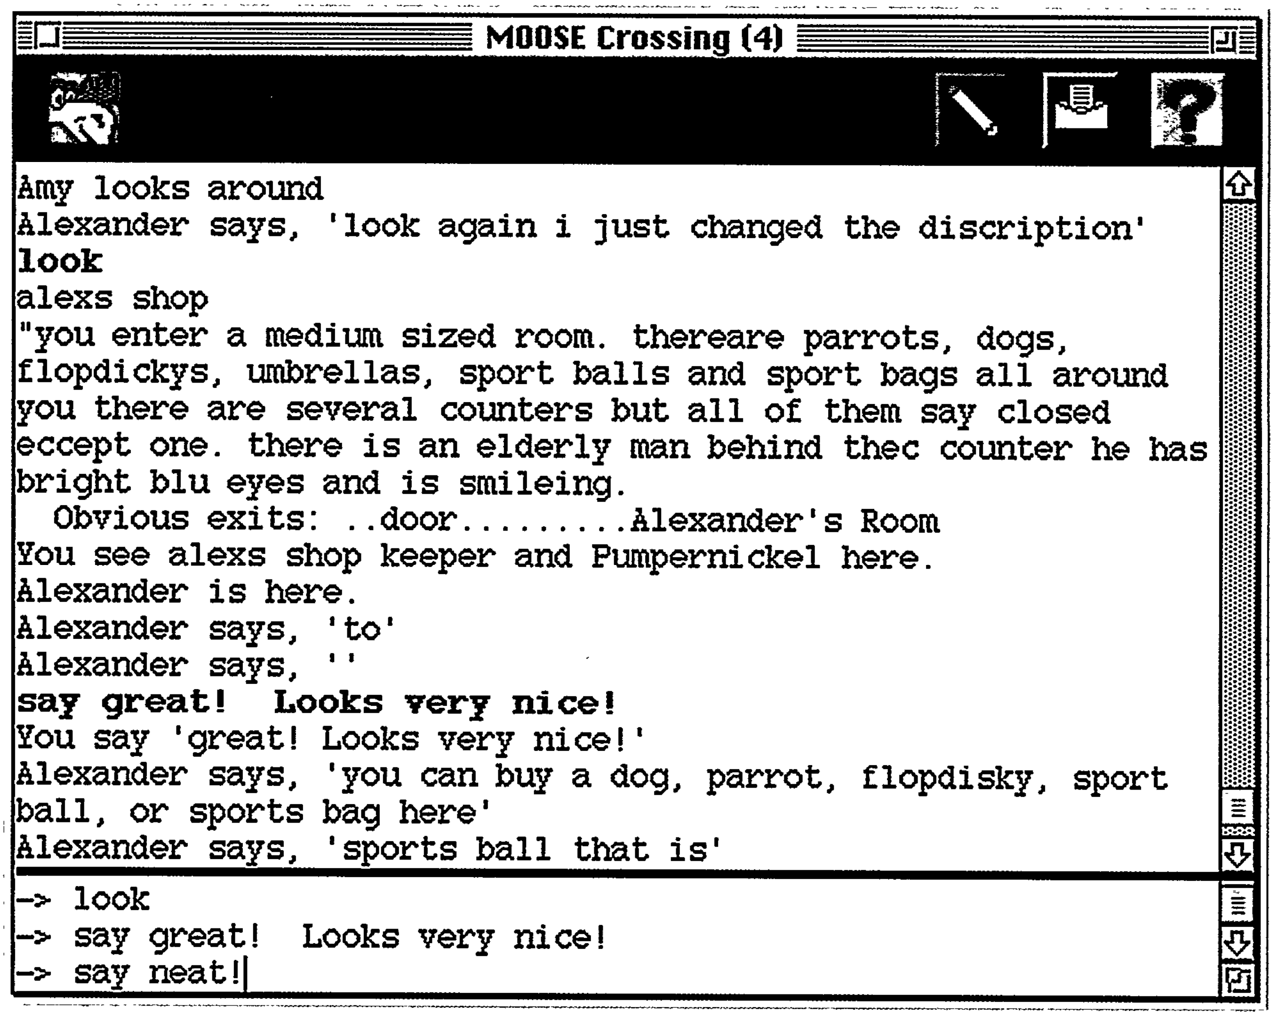
StarLogo makes these ideas accessible to younger students by providing them with a stronger personal connection to the underlying models. Traditional differential-equation approaches are "impersonal" in two ways. The first is obvious: they rely on abstract symbol manipulation. The second is more subtle: They deal in aggregate quantities. In the termite example, differential equations would describe how the density of wood chips evolves over time. There are now some very good computer modeling tools—such as Stella [13] and Model-It [4]—based on differential equations. These tools eliminate the need to manipulate symbols, focusing on more qualitative and graphical descriptions. But they still rely on aggregate quantities.

StarLogo, by contrast, lets students think about the actions and interactions of individual objects. StarLogo is not simply a computerization of a traditional mathematical model; it supports what we call "computational models"—models that wouldn't make sense without a computer. In the termite example, students think not about aggregate quantities but about individual termites and individual wood chips. They can imagine themselves as termites and think about what they might do. In this way, StarLogo enables learners to "dive into" the model, making a more personal connection. Future versions of StarLogo will enable users to zoom in and out, making it easier for users to shift back and forth in perspective from the individual level to the group level.

MOOSE CROSSING

Whereas StarLogo users typically build new worlds on their own or in pairs, MOOSE Crossing provides a way for children to build virtual worlds together as part of an online community.

MOOSE Crossing gives children the opportunity not only to "talk" with one another online, but also to collaboratively construct, with words and computer programs, the virtual world in which they interact [1]. MOOSE Crossing is similar to existing MUD environments [2], but it includes a new programming language (MOOSE) and new client interface (MacMOOSE) designed to make learning to program easier for kids. For each object that kids create, they write a combination of text and computer code to describe the properties and behaviors of the object. For example, one 12-year-old girl created a baby penguin that is always hungry. It responds differently when you offer it different kinds of food, and it won't eat certain foods if it is on a diet. A 9-year-old girl made a magical room at the end



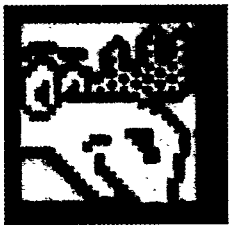
```
Amy looks around
Alexander says, 'look again i just changed the discription'
look
alexs shop
"you enter a medium sized room. thereare parrots, dogs,
flopdickys, umbrellas, sport balls and sport bags all around
you there are several counters but all of them say closed
eccept one. there is an elderly man behind thec counter he has
bright blu eyes and is smileing.
  Obvious exits: ..door.........Alexander's Room
You see alexs shop keeper and Pumpernickel here.
Alexander is here.
Alexander says, 'to'
Alexander says, ''
say great!  Looks very nice!
You say 'great! Looks very nice!'
Alexander says, 'you can buy a dog, parrot, flopdisky, sport
ball, or sports bag here'
Alexander says, 'sports ball that is'
```

```
-> look
-> say great!  Looks very nice!
-> say neat!
```

of the rainbow—answer the riddle correctly and you can take the pot of gold. Children help one another with their projects and share them with others excitedly. MOOSE Crossing places construction activities in a community context.

MOOSE Crossing is immediately appealing to many children because it draws on their personal connection to computer games, to elements of popular culture, and to socializing with each other. The environment has the feel of a text-based adventure game (and historically has its roots in such games), but it opens up greater intellectual challenges. You not only can experience the world but also build it. Children often choose popular culture as the subject of their conversations and an inspiration for their creations: for example, one afternoon, two 12-year-old girls started talking about *Star Trek* and decided to build themselves spaceships. Commercial culture is also a popular starting point for projects. One 11-year-old girl first made a vacation resort called Paradise Island, then set up a travel agency to sell people trips there, and last added a car rental agency. Several factors gave her a very personal connection to the project. It's important that she decided what she wanted to make: Rather than being assigned a project, she chose one that was personally meaningful to her. Her entire participation in MOOSE Crossing was voluntary—children participate in their spare time as an after-school activity. She was especially motivated by a desire to share her creation with other children. On finishing Paradise Island, she immediately invited all her online friends over for a swim. A successful project gives a child social capital within the community.

For more information about MOOSE Crossing see http://asb.www.media.mit.edu/people/asb/moose-crossing/



In each of these projects, children are doing creative writing and computer programming in their spare time for fun. MOOSE Crossing draws from children's natural interests to involve them in these intellectually valuable activities. They establish a new relationship to reading, writing, and programming. They begin to see them not just as something they are forced to do in school, but as expressive media through which they can make personally significant meanings. In other words, they establish a new epistemological relationship to these ways of understanding the world and expressing themselves.

MOOSE Crossing establishes new connections between different ways of knowing that are often separated and isolated in school activities. Making a successful MOOSE object is equal parts creative writing and computer programming. Making a MOOSE object helps children with a greater initial strength in one area develop greater confidence and competence in the other. One 9-year-old girl who says that she hates math and math-like activities loves programming on MOOSE Crossing because she sees it as a form of writing. Asked if she likes to write, she replied yes—in school she's writing stories about imaginary people, on MOOSE Crossing, she's writing programs. The only difference between these two kinds of writing is that "programming it everything has to be right so the thing you're making can work." She is bridging from her strong verbal skills to develop greater interest and skill in more analytic activities.

The children participating in MOOSE Crossing are mostly between 9 and 13 years old; a few children are as young as 7. Adults may apply to be "rangers." While we originally expected rangers to help children with their projects, in practice it more often works the other way around. Children have much more time to devote to MOOSE Crossing and generally understand better than adults how things work. Assisting an adult with a technical question is a real thrill for many kids and challenges some of their basic assumptions about learning. On MOOSE Crossing, everyone is playing, teaching, and learning all at the same time, rather like Seymour Papert's vision of activity in a "technological samba school" [8]. Knowledge is not passed from teachers to students but is developed by everyone through their activities and interactions with one another

Emergent Learning Experiences

Programmable bricks, StarLogo, and MOOSE Crossing are three very different types of computational construction kits. The first involves interaction with the physical world, the second involves the construction of virtual collaborations, and the third involves collaboration on virtual constructions. What unites these three diverse environments is their attempt provide both personal and epistemological connections. Each of these kits connects to student interests and experiences while also connecting to important intellectual ideas.

But the process of constructional design is not a simple matter of "programming in" the right types of connections. As students have used programmable bricks, StarLogo, and MOOSE Crossing, their learning experiences have been somewhat different than we (as developers) expected. This unpredictability is characteristic of constructional design. Developers of design-oriented learning environments need to adopt a relaxed sense of

Acknowledgments

Many members of the Epistemology and Learning Group at the MIT Media Laboratory have contributed to the ideas and projects described. In particular, Brian Silverman, Randy Sargent, and Andy Begel played central roles in the development of the programmable brick and StarLogo. The ideas here were influenced by conversations with Seymour Papert, Alan Kay, and Mike Eisenberg. The National Science Foundation (9153719-MDR and 9358519-RED) and the LEGO Group provided financial support for this research.

Educational designers cannot and should not control exactly what or when or how students will learn.

"control." Educational designers cannot and should not control exactly what or when or how students will learn. The point is not to make a precise blueprint. Rather, practitioners of constructional design can only create "spaces" of possible activities and experiences. What we can do as constructional designers is to try to make those spaces dense with personal and epistemological connections—making it more likely for learners to find regions that are both appealing and intellectually interesting.

In some ways, the design of a new learning environment is like the design of a StarLogo simulation. In creating StarLogo simulations, users write simple rules for individual objects, then observe the large-scale patterns that emerge. Users do not program the patterns directly. So too with constructional design. Developers of design-oriented learning environments cannot "program" learning experiences directly. The challenge, instead, is to create frameworks from which strong connections—and rich learning experiences—are likely to emerge.
