Window Manager Strategies

- ◆ Fixed
- Current
- Mouse

Mudibo Concept (CHI 2005)

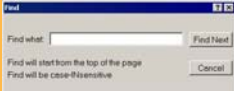

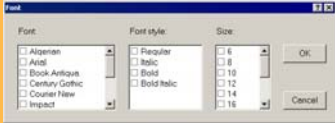

Hypothesis

Participants will be quicker to *interact* with Mudibo than with a single-placement approach.

Study – Setup – Equipment

Study Setup – Tasks

- Covers set of possible ideal dialog box placements
- Very repetitive – expect to see consistent strategies

Study Setup – Ordering

Time-~~rigid~~ trials

- 2 sets of 12 tasks, one set with Mudibo, one “Normal”
- Each condition explained to participant before starting
- Each set had 6 of each type of task in a pre-set order
- For Normal, half of DBs appeared on top, half to side

Study Outcome

Hypothesis

- Participants will be quicker to *interact* with Mudibo

Results (12 participants)

- 2.28 sec on average in Mudibo
- 3.03 sec on average in Normal
- $p < 0.01$ in one-tailed *t*-test
- 24% decrease in time (0.75 s)

Observations

Three basic strategy classes...

- (6) Move only when necessary
- (3) Always on top (before interaction)
- (3) Place based on task

... 10 of 12 failed to consistently use strategy

- Alterations
- Exceptions

Notable Behaviors

Move only when necessary

- 1 always picked a side monitor in Mudibo regardless of task type, with one additional exception

Always on top (before interaction)

- 1 had alteration of always leaving font (not find!) to side in the Normal set, with one additional exception

Discussion

Pre-set consistency doesn't match behavior;
Mudibo matches intent at decision-time

“Consistency”

- should it be redefined?
- should it be augmented?

Adaptive approaches

- is there ever enough context?
